# Ethernet moves to the plant floor

## Typical network requirements

**Plant** networks may span entire production facilities

- ▶ Connecting various nodes: office servers  $\leftrightarrow$  sensors/actuators

**Control** networks typically span plant floor

- ▶ Connecting specialized nodes

**Device** networks typically span parts of plant floor

- ▶ Connecting sensors and actuators

**Figure :** Typical network requirements at plant, control, and device levels

# Ethernet convergence

## Convergence in hardware and software standards

- ▶ More companies to support development
- ▶ All benefit from all
- ▶ Unifies and simplifies the wealth of field-buses
- ▶ Ubiquity reduces R&D, production, training, and maintenance costs
- ▶ Open standards may progress initiatives in open source projects and small/medium sized companies
- ▶ Get all the benefits of prior Ethernet R&D efforts for free

# The OSI reference model

## About the model

OSI (Open Systems Interconnection) model (ISO/IEC 7498-1)

- ▶ ISO: International Standards Organization
- ▶ IEC: International Electrotechnical Commission

Not a network architecture per se

- ▶ Comprises seven abstraction layers for communication
- ▶ Does not precisely specify services and protocols in each layer
- ▶ Just tells **in general** what each layer should do
- ▶ A layer serves the layer above it

Quite similar to the TCP/IP reference model

- ▶ Not a network architecture per se either

# The OSI reference model

## Ethernet's place in the model

	Layer	Data unit	Name	Function
Host layers	7	Data	Application	Meaning of data
	6		Presentation	Data representation and en/de-cryption. Machine de/inde-pendent data conversion
	5		Session	Interhost communication
	4	Segments	Transport	End to end connection, reliability and flow control
Media layers	3	Packet or datagram	Network	Determination of data paths within the network via logical addressing
	2	Frame	Data link	Data transmission via physical addressing, source, destination, and checksum
	1	Bit	Physical	Media (wire/fiber), signal connection, voltage levels, and binary transmission

Ethernet frame

Ethernet, IEEE 802.3

# The OSI reference model

## Communication in the model

- ▶ A layer serves the layer above it, i.e. layer  $L_n$  serves  $L_{n+1}$
- ▶ Service Data Units (SDU) are passed down from  $L_{n+1}$  to  $L_n$
- ▶  $L_n$  encapsulates  $L_{n+1}$  SDUs into protocol data units (PDU)
- ▶ A  $L_{n+1}$  SDU is embedded in the payload of a  $L_n$  PDU
- ▶ SDU is data sent by a user of the services of a given layer, and is transmitted semantically unchanged to a peer service user
- ▶  $L_n$  entity peers interact by the  $L_n$  protocol by transmitting PDUs

# Ethernet frame structure

- ▶ Payload includes all other protocol headers and footers
- ▶ Payloads less than 46 octets are padded
- ▶ 802.1Q for VLAN and quality of service prioritization
- ▶ **Video (5:23): Renepick, How to build an Ethernet Frame, 2013**

Preamble	Start of frame delimiter	MAC destination	MAC source	802.1Q tag (optional)	Ethertype (Ethernet II) or length (IEEE 802.3)	Payload	Frame check sequence (32-bit CRC)	Interframe gap
7 octets	1 octet	6 octets	6 octets	(4 octets)	2 octets	42 <sup>[note 2]</sup> –1500 octets	4 octets	12 octets
		64–1522 octets						
		72–1530 octets						
		84–1542 octets						

**Figure :** 802.3 Ethernet frame structure (Wikipedia).

# Protocol overhead and efficiency

Ethernet protocol efficiency =  $\frac{\text{Payload size}}{\text{Frame size}}$

- ▶ Good (nearly best) case:  $\frac{1500\text{octets}}{1542\text{octets}} = 97.28\%$
- ▶ Bad (nearly worst) case:  $\frac{46\text{octets}}{1542\text{octets}} = 2.98\%$

Other protocol headers in Ethernet payload, e.g.

- ▶  $\approx 8 \text{ (LLC)} + 20 \text{ (IP)} + 20 \text{ (TCP)} = 48 \text{ octets}$

E.g. add 48 header octets to send 10 yields 58 octets ( $> 46$ )

- ▶ Efficiency from payload perspective  $\frac{10\text{octets}}{1542\text{octets}} = 0.65\%$

# Ethernet timeline

- ▶ 1973: First versions of Ethernet developed at Xerox PARC
- ▶ 1975: Patent on Ethernet was filed by Xerox
- ▶ 1976: Ethernet deployed at PARC
- ▶ 1980: DIX (Digi. Equip. Corp/Intel/Xerox) std. v.1:  $10 \frac{\text{Mbit}}{\text{s}}$
- ▶ 1980: IEEE began R&D on LAN std. 802  
Different specs were promoted, e.g. CSMA/CD by DIX,  
Token Ring by IBM, Token Bus by GM
- ▶ 1985: IEEE std. 802.3 CSMA/CD was published. HDX
- ▶ 1990: In the decade, Ethernet became prevalent LAN tech.
- ▶ 1998: IEEE 802.3x introduced FDX
- ▶ 2011: Ethernet ubiquitous in home/industry: 0.1 and  $1 \frac{\text{Gbit}}{\text{s}}$

# Ethernet layout anno 1976

Robert Metcalfe presents Ethernet to the National Computer Conference in June 1976

**Video (9:14): The History of Ethernet, R. Metcalfe, 2007**

# Ethernet physical media examples

The original commercially available variant of Ethernet – no longer in use

## 10BASE5 (ThickNet)

- ▶ Coaxial cable with 9.5 mm diameter and  $50\Omega$  impedance
- ▶ Throughput of **10** Mbit/s
- ▶ **Baseband** digital transmission
- ▶ Maximum segment length of **500** m
- ▶ Maximum 100 nodes per segment

**Figure :** Transceivers, cables and tapping tool (Wikipedia)

# Ethernet physical media examples

## Other media examples

### 10BASE2 (ThinNet)

- ▶ Coaxial
- ▶ As 10BASE5 but cheaper and easier to install

### 10BASE-T (UTP)

- ▶ Full-duplex **U**nshielded **T**wisted **P**air
- ▶ Revision IEEE 802.3i completely new physical layer
- ▶ Also: 100Base-T/TX and 1000Base-T

### 10BASE-FL

- ▶ Full-duplex fiber-optic cable
- ▶ Also: 100Base-FX & 1000BASE-SX/LX

# Outline

Motivation and background

**Single segment Ethernet**

Multi segment Ethernet

Single segment real-time Ethernet

Multi segment real-time Ethernet

References

# Single segment Ethernet

- ▶ Originally single segment and HDX (< ca. 1990)
- ▶ CSMA/CD for sharing bandwidth on shared medium
- ▶ Speed is function of no. of simultaneously active nodes
- ▶ Collisions reduce throughput
- ▶ Packets are received by all. NIC filters per address
- ▶ During transmission: 1 node/time exclusive right to medium
- ▶ Damage to shared medium affects entire segment

# CSMA/CD - Carrier Sense

## Carrier Sense Multiple Access with Collision Detection

- ▶ Network interface card (NIC) listens for traffic on bus
- ▶ If traffic exist: Do not transmit
- ▶ If no traffic for a certain period (inter-frame gap): Transmit

# CSMA/CD - Multiple Access

## Carrier Sense Multiple Access with Collision Detection

- ▶ Multiple nodes on shared medium
- ▶ Collisions are highly likely
- ▶ All packets are passed by all nodes
- ▶ NIC filters: only addressee nodes receive data

# CSMA/CD - Collision Detection

## Carrier Sense Multiple Access with Collision Detection

- ▶ Collision occur if nodes send data simultaneously
- ▶ Nodes monitor own transmission
  - ▶ If node detects collision (high voltage signal)
  - ▶ Transmission stops and jam-signal broadcasted
  - ▶ Nodes discard packets and stops transmitting

# CSMA/CD - Collision Detection

## Carrier Sense Multiple Access with Collision Detection

Truncated binary exponential back-off algorithm

- ▶ To schedule retransmissions after detected collision
- ▶ Retransmit after a random number of slot-times:  
Max theoretical roundtrip time:  $t_{\text{slot}} = t_{\text{data out}} + t_{\text{jam back}}$
- ▶ Back-off after  $c \in [1; c_{\text{max}}]$  collisions:  $t_{\text{back-off}} = r \cdot t_{\text{slot}}$
- ▶ Where
  - ▶  $r \sim \mathcal{U}[0, \dots, 2^c - 1]$  where  $\mathcal{U}$  is the uniform PMF
  - ▶  $t_{\text{slot}} = 51.2\mu\text{s}$  at 10 Mbit/s
  - ▶  $t_{\text{slot}} = 5.12\mu\text{s}$  at 100 Mbit/s
- ▶ Truncated means
  - ▶ Ceiling on retransmission timeout
  - ▶ IEEE 802.3 CSMA/CD standard:  $c_{\text{max}} = 10$  (IEEE, 2008 [3])
  - ▶ Transmission canceled after 16 successive attempts and back-off interval reset to initial value

## Medium monopolization by back-off algorithm

- ▶ Two nodes A and B have a number of packets to transmit
- ▶ At some point a collision occur and, e.g. B randomly selects 0 and A selects 1 in  $[0;1]$
- ▶ Thus B will be successful in first retransmission
- ▶ B still has more packets to send and tries immediately to send again. By chance this collides with A
- ▶ A doubles the back-off interval whereas B uses the initial one. Thus B has higher chance of transmitting successfully
- ▶ This may repeat and B may monopolize the medium

# Summary of single segment Ethernet

## **Pros** in regard to real-time operations

- ▶ Low cost, flexible, and ubiquitous hardware

## **Cons** in regard to real-time operations

- ▶ CSMA/CD w/ random back-off algorithm
- ▶ Nondeterministic medium access timing makes it hard to guarantee deadlines
- ▶ No packet prioritization means that time-critical packets may yield for non-critical packets

## **Perspectives**

- ▶ Methods to counter the cons exist

# Outline

Motivation and background

Single segment Ethernet

**Multi segment Ethernet**

Single segment real-time Ethernet

Multi segment real-time Ethernet

References

# Main functionalities of a switch

## Micro-segmentation

- ▶ Separate collision domain for each network segment
- ▶ Only two nodes coexist in a collision domain
- ▶ Nodes have dedicated point-to-point bandwidth
- ▶ Full duplex without collisions

**Figure :** Industrial Ethernet switches from Moxa

# Micro-segmentation by switch

## Single segment vs. switched Ethernet

- ▶ One collision domain,  $C$ , for multiple nodes,  $N$
- ▶ Collisions are possible
- ▶ Non-deterministic

- ▶ One collision domain,  $C$ , per node,  $N$ , due to switch,  $S$
- ▶ Collision free
- ▶ Deterministic

# Conceptual switch internals

# Switched Ethernet

Fully switched means full-duplex Ethernet

- ▶ Collision-free: Only 2 nodes per collision domain
- ▶ Net speed is  $x$  bit/s  $\Rightarrow$  node-to-node is  $2x$  bit/s

Cabling

- ▶ Twisted-pair or fiber optic
- ▶ Separate transmit (Tx) and receive (Rx) conductors

# Switching methods on port basis

## Store and forward

- ▶ Entire packets buffered and checksum verified
- ▶ Corrupted packets dropped

## Cut through

- ▶ Reads only up to destination address before forwarding
- ▶ Forwards corrupted packets as checksum is not verified
- ▶ Higher speed than store and forward

## Adaptive switching

- ▶ If error rates low: Cut-through mode
- ▶ If error rates high: Store-and-forward mode

# Characteristics of switched traffic

## Corruption

- ▶ Bit errors by noise or interference
- ▶ Drops and retransmits packets in store and forward

## Latency

- ▶ Communication delay in media, e.g. wires, switches, routers
- ▶ Delay may build up even if throughput is approx. constant
- ▶ Ping command measures round-trip (NOOP) latency

## Packet delay variation (PDV)

- ▶ Low PDV: RT system may deal with latency by time offsets
- ▶ High PDV: Unpredictable and hard to guarantee deadlines

# Latency and packet loss example

```
--- goedel.math.ku.dk ping statistics ---  
5 packets transmitted, 5 received, 0% packet loss, time 4006ms  
rtt min/avg/max/mdev = 8.630/9.167/10.848/0.851 ms
```

```
--- www.monash.edu.au ping statistics ---  
5 packets transmitted, 5 received, 0% packet loss, time 4000ms  
rtt min/avg/max/mdev = 332.910/333.107/333.586/0.439 ms
```

**Figure :** Ping statistics

# Typical switch data

Port to port communication

- ▶ Less than 50  $\mu\text{s}$
- ▶ Depends on packet size

Packet delay variation

- ▶ Approximately 100 ns

## Latency: Single 100Mbit/s switch

- ▶ Min: (packet size, latency) = (64 Bytes, 10840 ns)
- ▶ Max: (packet size, latency) = (1518 Bytes, 126240 ns)

(Coley, 2004 [1])

# Latency: Multiple 100Mbit/s switches

(Coley, 2004 [1])

# Latency: Multiple Gbit/s switches

(Coley, 2004 [1])

# Latency: Connecting two switches

**Latency(Interconnect via switch versus router)**

- Routers read the address for proper routing

(Coley, 2004 [1])

# Nagle's algorithm

Increases bandwidth at the expense of latency

- ▶ Combines outgoing packets with small payloads
- ▶ Decreases overhead/pay-load ratio
- ▶ Good for normal Ethernet operations

Poor compliance with real-time systems

- ▶ Increases latency and packet delay variations

Disable / enable the algorithm

- ▶ Disable it: `TCP_NODELAY` socket option
- ▶ E.g. Unix `nc6` (netcat): Swiss army knife for TCP, UDP, ...
- ▶ “Client”: `nc6 -disable-nagle -l -p 1234`
- ▶ “Server”: `nc6 127.0.0.1 1234`

# Summary of multi segment Ethernet

## **Pros** in regard to real-time operations

- ▶ Fully switched gives full duplex
- ▶ No collisions: only two nodes in same collision domain
- ▶ Network segmentation via logical overlay virtual LAN
- ▶ Low cost, flexible, and ubiquitous hardware

## **Cons** in regard to real-time operations

- ▶ Deadlines hard to guarantee
- ▶ Arrival times of packets hard to predict
- ▶ Ethernet frames vary in size
- ▶ Unknowns: Route, latency, packet delay var., corruption ratio

## **Perspectives**

- ▶ Methods to counter the cons exist

# Outline

Motivation and background

Single segment Ethernet

Multi segment real-time Ethernet

References

# Single segment real-time Ethernet approaches

## Main challenge

- ▶ Collision avoidance on shared medium

## Common approaches

- ▶ Token based
- ▶ Time slot based
- ▶ Statistics based

See (Moraes, 2010 [4]) for a survey on real-time in CSMA networks

# Single segment real-time Ethernet

## Token based

Token represents permission to transmit

- ▶ Token circulated according to strategy
- ▶ Token management uses time and bandwidth
- ▶ Only one node may transmit at any time
- ▶ Limited performance vs. switched networks

# Single segment real-time Ethernet

## Time slot based

Time slot represents permission to transmit

- ▶ Time is divided according to strategy (TDMA)
- ▶ Strike a balance on time-slot lengths
  - ▶ Long: Long idle periods. Short: Frequent data partitioning
- ▶ Time management uses time and bandwidth
- ▶ Limited performance vs. switched networks

**Figure :** Stream into frames and time slots with data+guard (Wikipedia)

# Single segment real-time Ethernet

## Statistical based

- ▶ Keep network traffic low to bound probability of collisions
- ▶ Statistical guarantee to nodes for transmission time and bandwidth
- ▶ The overall network utilization decreases with stronger statistical guarantees
- ▶ Basically avoidance of invoking the back-off algorithm

# Outline

References

# Multi segment real-time Ethernet approaches

## Main challenge

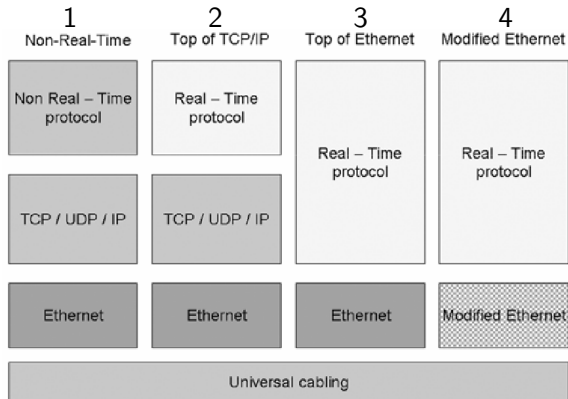

- ▶ Bandwidth control and scheduling, e.g. in switches

## Common approaches

- ▶ Profinet IRT
- ▶ EtherCAT
- ▶ Ethernet Powerlink
- ▶ Sercos III
- ▶ EtherNet/IP

# Classification of multi segment RTE approaches

## By protocol stacks

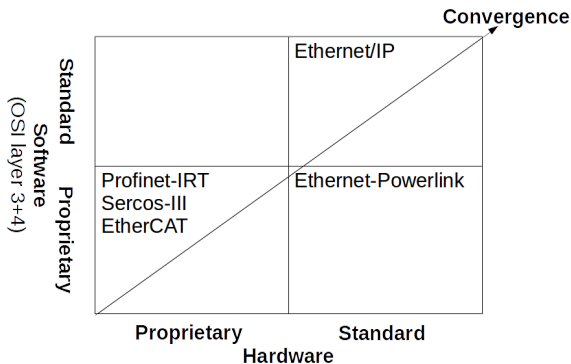

(Felser, 2005 [2])

1. No RTE overlay
2. Ethernet/IP
3. Ethernet Powerlink
4. Profinet v3, Sercos-III, EtherCAT

# Classification of multi segment RTE approaches

By hardware and software compliance

# Classification of multi segment RTE approaches

## By bandwidth control methods

### **Separate** slave polling

- ▶ Ethernet Powelink, ProfiNet IRT, Sercos-III

### **Combined** slave polling

- ▶ EtherCAT

### **Time** based

- ▶ Ethernet/IP (based entirely on standard Ethernet)

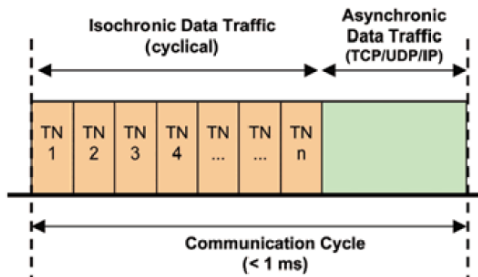

# Ethernet Powerlink, ProfiNet IRT, and Sercos III

## Separate slave polling

Per cycle

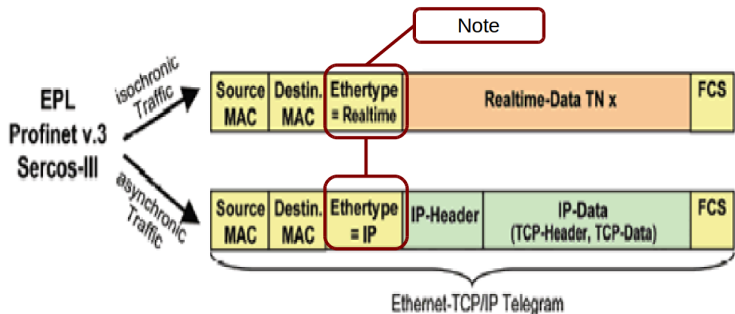

- ▶ RT traffic: Master polls each slave with an Ethernet telegram
- ▶ Non-RT traffic: Remaining cycle time

**Figure :** Time slot mechanism

# Ethernet Powerlink, ProfiNet IRT, and Sercos III

## Separate slave polling

**Figure :** Telegram structuring

## Ethertype

- ID of protocol encapsulated in the Ethernet frame payload

# EtherCAT

## Combined slave polling

Per cycle

- ▶ RT traffic: Master polls slaves with an Ethernet telegram shared by all
- ▶ Non-RT traffic: Space reserved as a sub-telegram in the shared telegram

**Figure :** Telegram structuring

# EtherCAT

## Combined slave polling

- ▶ Designed for small payloads per node
- ▶ One Ethernet frame holds more sub-frames
  - ▶ Encoded and decoded by special hardware
  - ▶ Slaves read and write in same sub-frame on the fly
- ▶ Each with payloads for nodes in the network
  - ▶ Reduces overhead/payload ratio
- ▶ Synchronization via distributed clock
  - ▶ Very low packet delay variations

# EtherNet/IP

## Time based

### Ethernet/IP

- ▶ Based entirely on standard Ethernet
- ▶ Synchronized clocks via Precision Time Protocol
- ▶ Control commands must be received by slaves in due time
- ▶ RT delivery by master by UDP
- ▶ QoS prioritization of traffic (802.1Q)

# EtherNet/IP

## Time based

Preamble	Start of frame delimiter	MAC destination	MAC source	802.1Q tag (optional)	Ethertype or length	Payload	Frame check sequence (32-bit CRC)	Interframe gap
7 octets of 10101010	1 octet of 10101011	6 octets	6 octets	(4 octets)	2 octets	46-1500 octets	4 octets	12 octets

**Figure :** QoS prioritization in Ethernet frame; switches prioritize traffic

**Figure :** Precision Time Protocol for clock synchronization

# Comparison of approaches in real-time setup

- ▶ Setup: 100 axles to be controlled synchronously
- ▶ Response time: Cycle time
- ▶ Jitter: Variations in response time
- ▶ Conclusion: More proprietary → Faster and less jitter

Organization	Response time (for 100 axles)	Jitter	Data rate
<b>Ethernet/IP</b> CIPSync ODVA	$\approx 1\text{ms}$	$<1\text{ms}$	100Mbit/s
<b>Ethernet Powerlink</b> EPG	$<1\text{ms}$	$<1\text{ms}$	100Mbit/s
<b>Profinet-IRT</b> PNO	$<1\text{ms}$	$<1\text{ms}$	100Mbit/s
<b>Sercos-III</b> IGS	$<0.5\text{ms}$	$<0.1\text{ms}$	100Mbit/s
<b>EtherCAT</b> ETG	$\approx 0.1\text{ms}$	$<0.1\text{ms}$	100Mbit/s

## Comparison of approaches in real-time setup

- ▶ Setup: Field bus vs. Ethernet
- ▶ No. of slave pollings measured in no. of packets/ms
- ▶ Performance criteria: Theoretical packet throughput (actual throughput lower due to processing and latency)
- ▶ Conclusion: New Ethernet based systems perform well

	Transfer rate	Packet size <i>with 8 bytes of user data</i>	Theoretical packet throughput
<b>Profibus DP</b>	12 Mbit/s	19 bytes	79 packets/ms
<b>Sercos-II</b>	16 Mbit/s	14 bytes	142 packets/ms
<b>Ethernet</b>	100 Mbit/s	72 bytes	174 packets/ms
